## TRUST Baltik Project Tutorial V1.8.2beta

**CEA Saclay** 

Support team: trust@cea.fr

December 10, 2020

- TRUST initialization
- 2 Eclipse initialization
- 3 Create a Baltik project
- 4 Modify the cpp sources
- Parallel exercise
- 6 PRM file and validation test case
- Code coverage exercise
- Tools
- For more

## TRUST initialization

- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Create a Baltik project
  - Creation of a Baltik project
  - Creation of your git repository
  - Builds
  - Using Eclipse
- Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
- PRM file and validation test case
  - "trust -prm"
  - Validation test case
- Code coverage exercise
- Tools
  - Debug with GDB
  - Find memory bugs with valgrind

## TRUST initialization

### TRUST commands

- Load TRUST environment:
  - On CEA Saclay PCs, TRUST versions are available with (e.g. X.Y.Z=1.8.1):
     source /home/triou/env TRUST X.Y.Z.sh
  - On your own computer, download and install the latest version of TRUST in your local folder \$MyPathToTRUSTversion (unless this was already performed), then write on the terminal: source \$MyPathToTRUSTversion/env TRUST.sh

Ensure that the configuration is ok and locate the sources:

- \$ echo \$TRUST\_ROOT
- Now, copy a TRUST test case that we will need later:
  - \$ mkdir -p Formation\_TRUST/yourname
  - \$ cd Formation\_TRUST/yourname
  - \$ trust -copy upwind
  - \$ cd upwind
  - Replace "format Iml" by "format lata" in the data file

- TRUST initialization
- 2 Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Creation of a Baltik project
  - Creation of your git
  - repository
  - Builds
  - Using Eclipse
- Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
- PRM file and validation test case
  - "trust -prm"
  - Validation test case
- Code coverage exercise
- Tools
  - Debug with GDB
  - Find memory bugs with valgrind

## Download Eclipse

### Download Eclipse

- Visit the Eclipse Foundation website: http://www.eclipse.org/downloads/eclipse-packages/
- Click on Eclipse Neon (4.6) on the menu More downloads.
- Select Eclipse IDE for C/C++ Developers → Linux 64-bits
- Download the eclipse-cpp-neon-3-linux-gtk-x86\_64.tar.gz package in your directory Formation\_TRUST/yourname
- For OS older than CentOs7, Ubuntu16.04 and Fedora22, download Eclipse
   Mars version: eclipse-cpp-mars-2-linux-gtk-x86 64.tar.gz

### Untar the downloaded archive

```
$ cd Formation_TRUST/yourname
```

- \$ tar xfz eclipse-\*.tar.gz
- \$ cd eclipse

## Configure Eclipse

### For Ubuntu16.04, Fedora22, CentOs 7 and recents OS

Edit the *eclipse.ini* file by deleting the last 2 lines (Xms and Xmx) and adding the following lines:

Xms512m

Xmx2048m

### For older OS

Edit the *eclipse.ini* file, by deleting the last 3 lines (MaxPermSize, Xms and Xmx) and adding the following ones:

Xmn256m

Xss2m

server

Xms512m

Xmx2048m

- TRUST initialization
- 2 Eclipse initialization
  - Download& configure eclipse

# Create a TRUST platform project under Eclipse (I)

### On a terminal

Load TRUST environment and copy "upwind" test case as described on p.4:

- \$ echo \$TRUST\_ROOT/src
- \$ echo \$exec\_debug

### Launch Eclipse

- \$ mkdir -p Formation\_TRUST/yourname/workspace
- \$ cd Formation\_TRUST/yourname/eclipse
- \$ ./eclipse &
  - Workspace: Browse the directory Formation\_TRUST/yourname/workspace
  - Welcome : close x button

# Create a TRUST platform project under Eclipse (II)

## Create the project

- File  $\rightarrow$  New  $\rightarrow$  C++ Project
  - ⇒ Project name: TRUST-X.Y.Z (e.g.: TRUST-1.8.1)
  - $\Rightarrow$  Project type: "Executable"  $\rightarrow$  "Empty Project"
  - ⇒ Toolchains: "Linux GCC"
  - $\Rightarrow$  Finish

## Import TRUST source files into the project

- ullet From the "Project Explorer" tab, right click on TRUST-X-Y-Z ightarrow "Import..."
  - $\Rightarrow$  General  $\rightarrow$  File System  $\rightarrow$  Next
  - ⇒ From directory: copy the string matching \$TRUST\_ROOT/src/
  - ⇒ Check "Select All"
  - ⇒ Into folder: TRUST-X.Y.Z
  - $\Rightarrow$  Finish
  - $\Rightarrow$  Wait to have 100% at the bottom right corner of the window (C/C++ indexer).

# Create a TRUST platform project under Eclipse (III)

## Configure the project and launch a computation

- From the "Project Explorer" tab, right click on TRUST-X.Y.Z → Properties
  - $\Rightarrow$  Builders: uncheck "CDT Builder"  $\rightarrow$  OK  $\rightarrow$  OK
- $\bullet$  From the "Project Explorer" tab, right click on TRUST-X.Y.Z  $\to$  "Debug As"  $\to$  "Debug Configurations..."
  - $\Rightarrow$  Right click on "C/C++ Application"  $\rightarrow$  New
    - In the "Main" tab (tell Eclipse which binary will be used):
      - ⇒ Project: TRUST-X.Y.Z
      - $\Rightarrow$  "C/C++ Application": copy the string matching \$exec\_debug
      - $\Rightarrow$  "Apply"
    - In the "Arguments" tab (tell Eclipse which datafile to run):
      - $\Rightarrow$  "Program arguments"  $\rightarrow$  specify datafile's name (here upwind)
      - $\Rightarrow$  "Working directory"  $\rightarrow$  uncheck "Use default" and type path to datafile
      - ⇒ "Apply"
  - $\Rightarrow$  "Debug" : your datafile will be run with the specified executable

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- 3 Create a Baltik project
  - Creation of a Baltik project
  - Creation of your git repository
  - Builds
  - Using Eclipse
- Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
- PRM file and validation test case
  - "trust -prm"
  - Validation test case
- Code coverage exercise
- Tools
  - Debug with GDB
  - Find memory bugs with valgrind

## Creation of a Baltik project

## Create an empty Baltik

- Create a directory for your project:
  - \$ cd Formation\_TRUST/yourname
- Create your project from a basic project template using TRUST commands:
  - \$ trust -baltik my\_project
  - \$ cd my\_project
  - \$ ls -1

You can see that you have now:

- o three directories: share, src and tests, and
- o one "project.cfg" file.
- one "RFADMF BALTIK" file.
- o one "configure" script.

## Add sources to your Baltik

- Copy the following TRUST .cpp file into your baltik project:
  - \$ mkdir -p src/TRUST\_modif
  - \$ cp \$TRUST\_ROOT/src/MAIN/mon\_main.cpp src/TRUST\_modif/

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Create a Baltik project
  - Creation of a Baltik project
  - Creation of your git repository
  - Builds
  - Using Eclipse
- 4 Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- PRM file and validation test case
  - "trust -prm"
  - Validation test case
- Code coverage exercise
- Tool
  - Debug with GDB
  - Find memory bugs with valgrind

# Create your git repository

### Git commands

You will now create a git repository to manage your developments.

- Initialize an empty git repository:
  - \$ git init
- Display your working tree status:
  - \$ git status
- You can see 3 file and src directory on the "untracked" files section. It means that they are not yet followed by the git repository.
- Add src and project.cfg to your git repository in order to prepare a commit: \$ git add src project.cfg
- Now, you can commit your files to add it to your git repository: \$ git commit -m "Initial commit" Remark: If you are not able to commit files, you should first configure your username and email in git with:
  - git config --global user.name "Your Name"
  - git config --global user.email you@example.com

## Create your git repository

### Git commands

- Display your working tree status:
  - \$ git status
    Only README F
  - Only README.BALTIK and configure script (automatically generated) are not added to your git repository.
- Display the list of commits:
  - \$ git log

### Baltik commands

- Edit your project file "project.cfg" to specify name, author and executable.
- Then configure your project:
  - \$ baltik\_build\_configure -execute
    this command launches both scripts: the "baltik\_build\_configure" and
    "configure".

## Create your git repository

#### Git commands

- Check the status of your git repository with the "--ignored" option to see the status of all files:
  - \$ git status --ignored
- You can see that
  - "project.cfg" has been modified.
  - there are new untracked files: these files are not on the git repository
- To see only the changes on the git repository files:
  - \$ git status -uno
- Track changes via gitk (GUI interface of Git):
  - \$ gitk &

You can see information about your first commit and actual untracked changes.

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Create a Baltik project
  - Creation of a Baltik project
  - Creation of your git repository
  - Builds
  - Using Eclipse
- Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
- PRM file and validation test case
  - "trust -prm"
  - Validation test case
- Code coverage exercise
- Tools
  - Debug with GDB
  - Find memory bugs with valgrind

### Make a basic build

- To make a basic build:
  - \$ cd Formation\_TRUST/yourname/my\_project
- Configure your project:
  - \$ ./configure
- Build your project in different modes:
  - Build an optimized (-03 option) version:
    - \$ make optim
  - Build a debug (-g -O0 option with asserts) version:
    - \$ make debug
- Initialize your baltik project environment:
  - \$ source env\_my\_project.sh
- Check that executables are available:
  - \$ ls \$exec
  - \$ ls \$exec\_opt
  - \$ ls \$exec\_debug

### Other builds

- List other options available for the make command:
  - \$ make help
- Build an :
  - optimized binary for profiling (option -pg -O3):
    - \$ make prof
    - \$ ls \$exec\_pg
  - optimized binary for test coverage (option -gcov -O3):
    - \$ make gcov
    - \$ ls \$exec\_gcov

Notice that TRUST optimized binary for profiling or a TRUST optimized binary for test coverage must exist in order to be able to compile your baltik's profiling or test coverage executable.

# Create a basic BALTIK project without dependency (I)

## Initialize baltik environnement

```
$ source env_my_project.sh
```

\$ echo \$project\_directory/src

## Launch Eclipse

```
$ cd Formation_TRUST/yourname/eclipse
```

\$ ./eclipse &

## Create the project

- ullet File o New o "Makefile Project with Existing Code"
  - ⇒ Project name: MY BALTIK
  - ⇒ Existing Code Location: copy string matching \$project\_directory/src
  - ⇒ Toolchain for Indexer Settings: "Linux GCC"
  - $\Rightarrow$  Finish
  - $\Rightarrow$  Wait to have 100% at the bottom right corner of the window (C/C++ indexer).

# Create a basic BALTIK project without dependency (II)

## Configure the BALTIK project and link it with TRUST

- ullet From the "Project Explorer" tab, right click on MY\_BALTIK o Properties
  - ⇒ Builders: check "CDT Builder"
  - $\Rightarrow$  C/C++ Build :
    - Builder Settings: Build directory: \${workspace\_loc:/MY\_BALTIK}/../ or copy the string matching \$project\_directory/
    - Behavior: check "Build (Incremental build)": debug optim (instead of all)
  - ⇒ Project References: check TRUST-X.Y.Z → OK

## Build the BALTIK project

From the "Project Explorer" tab, right click MY\_BALTIK  $\rightarrow$  Index  $\rightarrow$  Rebuild  $\Rightarrow$  Wait to have 100% at the bottom right corner of the window (C/C++ indexer).

Right click MY BALTIK → Build Project

# Create a basic BALTIK project without dependency (III)

### Launch a computation

- $\bullet$  From the "Project Explorer" tab, right click MY\_BALTIK  $\to$  "Debug As"  $\to$  "Debug Configurations..."
  - $\Rightarrow$  C/C++ Application  $\rightarrow$  New
    - In the "Main" tab:
      - ⇒ Project: MY\_BALTIK
      - $\Rightarrow$  C/C++ Application:  $\scriptstyle \$  workspace\_loc:/MY\_BALTIK}/../my\_project or copy the string matching  $\scriptstyle \$  exec\_debug
      - ⇒ "Apply"
    - In the "Arguments" tab:
      - $\Rightarrow$  Program arguments  $\rightarrow$  specify the name of your datafile (upwind)
      - $\Rightarrow$  Working directory  $\rightarrow$  uncheck "Use default" and type path to datafile's directory
      - ⇒ "Apply"
  - $\Rightarrow$  Debug

## Useful shortcuts in sources

#### **Shortcuts**

- Open a cpp file from Project Explorer tab: Double click on TRUST-X.Y.Z  $\rightarrow$  Kernel  $\rightarrow$  Framework  $\rightarrow$  Probleme base.cpp
- In the cpp file: Right click on method "initialize()"
  - ⇒ F3: Opens Declaration
  - ⇒ F4: Open Type Hierarchy
  - ⇒ Ctrl+Alt+H: Open Call Hierarchy
  - $\Rightarrow$  "Alt+ $\rightarrow$ " and "Alt+ $\leftarrow$ ": Move from a tab to another

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Create a Baltik project
  - Creation of a Baltik project
  - Creation of your git repository
  - Builds
  - Using Eclipse
- 4 Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
- PRM file and validation test case
  - "trust -prm"
  - Validation test case
- Code coverage exercise
- Tool
  - Debug with GDB
  - Find memory bugs with valgrind

#### Baltik commands

- Create a new folder for your own classes:
  - \$ mkdir -p \$project\_directory/src/my\_module
  - \$ cd \$project\_directory/src/my\_module
- Create your first class "my first class" with template:
  - \$ baltik\_gen\_class my\_first\_class

#### Git commands

- Display the status of your repository:
  - \$ git status .
- Add your new class to your git repository to follow your modifications:
  - \$ git add my\_first\_class.\*
  - \$ git commit -m "Add my\_first\_class src"

### Baltik commands

- Have a look at the 2 files my\_first\_class.h|cpp.
- Each time a source file is added to the project, you need to configure it:
  - \$ cd \$project\_directory
  - \$ ./configure
- Build your project with Eclipse or in the terminal.
- Edit the 2 files with vim|nedit|gedit|emacs.

### **Eclipse**

- Edit the 2 files with Eclipse.
- For Eclipse use, you have to update your project to see your new files:
  - → "Index/Rebuild" from "my project" of "Project Explorer"
  - → Click on "▶" button of "my project" in the "Project Explorer"

#### Baltik commands

- We want to change the inheritance of the class in order that it inherits from "Interprete geometrique base" class instead of "Objet U".
  - "Interprete geometrique base" class is the base class of all the keywords doing tasks on domains (eg: Mailler, Lire fichier,...).

## So:

- o add an "#include <Interprete geometrique base.h>" in my first class.h,
- o switch "Objet U" to "Interprete geometrique base" in the .h and .cpp files,
- rebuild your application.
- An error will occur!

This error indicates that a pure virtual function ("interpreter") should be implemented.

- Look at the "Interprete geometrique base" class:
  - Eclipse: highlight the string "Interprete geometrique base" and push the F3 button of your keyboard to open the declaration file of this class
  - Or with the HTLM documentation: open the declaration file of the "Interprete geometrique base" class

### Baltik commands

Look at "interpreter()" method, which calls the "interpreter\_()" method.
 This method is called each time a keyword is read in the data file (eg: "Read file dom dom.geom", "Solve pb",...).

• Define the public method "interpreter (Entree&)" in the include file and

- implement it (just print a message with "Cerr" like "- My first keyword!") into the cpp file.

  "Entree" is a TRUST class to read an input stream (from a file for example):
  - "Entree" is a TRUST class to read an input stream (from a file for example) "virtual Entree& interpreter\_(Entree&);"
- Rebuild your project and fix your files until the binary of your project is built

## Test your new class

- Copy a test case to the build folder of your Baltik project:
  - \$ cd \$project\_directory/build/
  - \$ trust -copy Cx
  - ERROR...

### Test your new class

- The error occurs because this test case is not in your baltik but in TRUST project. To be able to copy it, you have to load the full environment (TRUST+our baltik).
  - \$ source ../full\_env\_my\_project.sh
  - \$ trust -copy Cx
  - \$ cd Cx
- Edit the data file:
  - \$ nedit Cx.data &
  - Add keywords "my\_first\_class" and "End" after the line where the problem is discretized.
  - NB: Instead of "End", you can reduce the number of time steps to only 1.
- Run this datafile with your baltik binary to check that this new keyword is recognized (see next slide).

## With Eclipse:

- → In the project explorer, right click on "MY BALTIK" and select "Debug As/Debug configurations..."
- ightarrow In "Main" tab, check "Disable auto build" then click on "Apply"
- → In "Arguments" tab, fill "Program arguments:" with "Cx"
- → "Working directory:" Copy the path to datafile matching
- \$project directory/build/Cx
- $\rightarrow$  "Apply" and "Debug"
- $\rightarrow$  Click on "Yes" to change the kind of view
- $\rightarrow$  Click on "Resume" button to run the calculation until the end

### On a terminal:

```
$ cd $project_directory/build/Cx/
```

\$ exec=\$exec\_debug trust Cx

Nota bene: "Interprete geometrique base::interpreter ()" method is called first, then it calls "my first class::interpreter ()" method.

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Create a Baltik project
  - Creation of a Baltik project
  - Creation of your git repository
  - Builds
  - Using Eclipse
- 4 Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
  - PRM file and validation test case
    - "trust -prm"
    - Validation test case
- Code coverage exercise
- Tool
  - Debug with GDB
  - Find memory bugs with valgrind

## Modify your cpp class

#### Part 1

 To be able to read object parameters from the datafile using the following syntaxe for example:

```
A a Read a { dimension 3 option fast }
```

it is recommended to use **Param** objects as shown on the next slide. Here, the reading of parameters is done by the readOn method.

• Param use is the recommended choice in this case (even though many current TRUST classes are still using the old fashion to read parameters), because it greatly simplifies the coding.

## Modify your cpp class

## Part 1: Example of Param use

```
#include <Param h>
Entree& A::readOn(Entree& is)
Nom opt;
int dim;
Cerr << "Reading parameters of A from a stream (cin or file)" << finl;
Param param(que_suis_je());
// Register parameters to be read:
param.ajouter("option", & opt);
param.ajouter("dimension",&dim,Param::REQUIRED);
// Read now the parameters from the stream is and produces an error
// if unknown keyword is read or if braces are not found at the
// beginning and the end:
param.lire_avec_accolades_depuis(is);
. . .
return is;
```

## Modify your cpp class

### Part 1

 In our case, the read of the parameters will be done by the interpreter() method so the syntax in the data file will be the following:

```
my_first_class { domaine dom option 0 }
# dom is the domain name #
```

- Add into the "interpreter\_(Entree&)" method the read of these parameters into braces using the Param object.
  - Do not forget to add "#include <Param.h>" into the cpp file.
  - If help needed, have a look at the "Interprete\_geometrique\_base" sub-class "Extruder". The data file syntax is:

```
Extruder { domaine DomainName nb tranches N direction X Y Z }
```

#### Part 1

- Now we want to obtain the domain object using its name.
  - You can have a look at the following method:
     Interprete geometrique base::associer domaine ( Nom & nom dom)
  - Look the HTML documentation.
     What is the task of this method?
- Once implementation is finished, add a check at the end of the method "interpreter (Entree&)" and find how to print the domain name:

```
Cerr << "Option number " << option_number << " has been
read on the domain named " << ??? << finl;</pre>
```

#### Part 1

- With Eclipse:
  - Build/fix/re-build your project:
    - $\rightarrow$  "Project" and "Build project"
  - Run the test case:
    - ightarrow "Run" and "Debug"
- Or in a terminal:
  - Build/fix/re-build your project:
    - \$ cd \$project\_directory
    - \$ make debug
  - Run the test case:
    - \$ cd \$project\_directory/build/Cx/
    - \$ export exec=\$exec\_debug
    - \$ trust Cx
    - In this case, TRUST runs with exec debug.

### Part 2: Display information about domain boundaries

- Edit the "my\_first\_class.cpp" file and add into the "interpreter\_()" method
  a loop on the boundaries.
   Look for help inside the "Domaine", "Zone", "Bord", "Frontiere" classes in
  - the HTML documentation to access to the:
    - Number of boundaries (nb\_bords() method)
    - Boundaries (bord(int) method)
    - Name of the boundaries (le\_nom() method)
    - Number of faces of each boundary (nb faces() method)

Print these information with something like:

```
Cerr << "The boundary named " << ??? << " has " << ??? << "
faces." << finl;</pre>
```

### Part 2: compute the sum of the domain's VEF control volumes

Information about control volumes is in the "Zone\_VF" class (a "Zone\_dis" discretized zone) which can't be accessed from the domain, but only from the problem.

So, you need to read another parameter in your data file:

```
my_first_class { domaine dom option 0 problem pb }
```

- Add the read of a new parameter problem into "my\_first\_class.cpp" file (see "Extraire\_plan::interpreter\_(Entree&)" method for instance).
- Remember the "equation" or "problem" UML diagram of the presentation's slides.
- Look for help inside the "Zone\_VF", "Probleme\_base" and "Equation base" into the HTML documentation to access to the:
  - equation (equation(int) method)
  - o discretized zone (zone dis() method)
  - o control volumes (volumes entrelaces() method)

#### Part 2

- You will need to cast the discretized zone returned by the zone\_dis()
  method into a "Zone VF" object.
- Print the size of the control volumes array with something like:

```
Cerr << control_volumes.size() << finl;</pre>
```

Where control\_volumes is a **DoubleVect** returned by the **Zone VF::volumes entrelaces()** method.

- If you look at the "Problem" UML diagram of the presentation's slides, you will notice a better path to access to the discretized zone.
   What is this path?
- Now, compute and print the sum of the control volumes with a "for" loop.

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Create a Baltik projectCreation of a Baltik project
  - Creation of your git
  - repository
  - Builds
  - Using Eclipse
- Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
  - PRM file and validation test case
    - "trust -prm"
    - Validation test case
- Code coverage exercise
- Tool
  - Debug with GDB
  - Find memory bugs with valgrind

### Create automated documentation

- We want now to add XData tag to create the automated documentation of your new code.
- First we have to create this documentation for the first time.
  - \$ cd \$project\_directory
  - \$ make gui
- Open the documentation file:
  - \$ evince \$project\_directory/build/xdata/XTriou/doc.pdf &
- Now we will add comments in our cpp files to add information in the documentation.
- For this open the help of the TRAD\_2 syntaxe:
   \$ gedit \$project\_directory/build/xdata/XTriou/doc\_TRAD\_2 &

4 D > 4 B > 4 B > 3 B > 9 Q P

### Create automated documentation

 Add a first tag (in comments) into your cpp file just after the openning brace of the 'interpreter\_()' method:

```
// XD english_class_name base_class_name TRUST_class_name
mode description
```

- The "english\_class\_name" and "TRUST\_class\_name" can be "my first class".
- The "base\_class\_name" is the name of the section in which will appear the information of your new class in the 'doc.pdf' file.
- The "mode" is to choose with the help of the doc\_TRAD\_2 file. Here we use "-3".

### Create automated documentation

Then add at the end of the lines of type "param.ajouter...", an XD comment like:

```
param.ajouter(...); // XD_ADD_P type description
where "type" can be (cf 'doc_TRAD_2' file): 'int', 'floattant', 'chaine',
'rien'...
```

- Compile the documentation:
  - \$ make gui
- Check that the documentation of your new class is in the new doc:
   \$ evince \$project\_directory/build/xdata/XTriou/doc.pdf &
- To check that the GUI is validated:make check\_gui
- Notice that you must have XD commands in all your cpp classes.

- TRUST initialization

  - Debug with GDB
  - Find memory bugs with valgrind

- Edit the "\$project\_directory/src/TRUST\_modif/mon\_main.cpp" file of your baltik project using text editor or Eclipse.
- Add these lines after "Process::imprimer\_ram\_totale(1);" : std::cout << "Hello World to cout." << std::endl; std::cerr << "Hello World to cerr." << std::endl; Cout << "Hello World to Cout." << finl; Cerr << "Hello World to Cerr." << finl; Process::Journal() << "Hello World to Journal." << finl;</p>

#### in a terminal: Rebuild the code

- \$ cd \$project\_directory
- \$ make debug optim

- Create an empty data file:
  - \$ mkdir -p \$project\_directory/build/hello
  - \$ cd \$project\_directory/build/hello
  - \$ touch hello.data
- Run the code
  - sequentially:
    - \$ trust hello
  - in parallel:
    - \$ trust hello 4

and see the differences.

- "Cout" is equivalent to "std::cout" on the master process only. Use this
  output for infos about the physics (convergence, fluxes,...).
- "Cerr" is equivalent to "std::cerr" on the master process only. Use this output for warning/errors only.
- "finl" is equivalent to "std::endl" + "flush()" on the master process.
- "Journal()" prints to "datafile\_000n.log" files. Use this output during parallel development to print plumbing infos which would be hidden during production runs.

- During a parallel run, the "Journal()" output can be disabled.
   To verify this, first clean your folder:
  - \$ ls \*.log
  - \$ trust -clean
  - and run computation with -journal=0 option
  - \$ trust hello 4 -journal=0
  - \$ ls \*.log
- Other options are available. To get it, run:
  - \$ trust hello.data -help\_trust

### Printing into a file

- Now, we will print the control volumes sum into a file for test case Cx.
- We want to write in a file with name similar to: DataFileName\_result.txt where "DataFileName" is the name of the data file (eg: Cx).
- For that, you will:
  - create an object of the class Nom and fill it by collecting the datafile's name using Objet U::nom du cas() method.
  - complete the datafile's name with the string "\_result.txt" thanks to the "operator+=" method of the class Nom.
  - create the output file with the **SFichier** class and print the sum into it.
- Compile your project and run Cx datafile:
  - \$ cd \$project\_directory/build/Cx/
  - \$ exec=\$exec\_debug trust Cx
- Then open the "Cx result.txt" file.

- TRUST initialization
- 2 Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Create a Baltik project
  - Creation of a Baltik project
  - Creation of your git repository
  - Builds
  - Using Eclipse
- Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- 6 Parallel exercise
  - PRM file and validation test case
    - "trust -prm"
    - Validation test case
  - Code coverage exercise
- Tools
  - Debug with GDB
  - Find memory bugs with valgrind

#### Part 1

- Run your test case Cx in parallel mode:
  - \$ cd \$project\_directory/build/Cx/
  - \$ trust -partition Cx 2 # Partition in 2 subdomains
  - \$ trust PAR\_Cx 2 # 2 processes used
- Compare the files: Cx\_result.txt, PAR\_Cx\_result.txt.
   Differences come from the fact that the 2 processors write into the file one after the other one. So the final content will be the value calculated on the last processor which will acces to the file.
- You can try to launch one more time the calculation, the result may differ.
- To have the entire sum, you can apply the mp\_sum() method on the sum obtained and add the print in the .txt file.
- Compare it to the sum obtained in the sequential run.
- It is better but we counted several times faces that belongs to the joint and to the virtual zones.

### Part 1

- To parallelize the algorithm, rewrite it with the help of the mp\_somme\_vect(DoubleVect&) method.
- Add this print in the .txt file.
- You should find the same value for the sequential and parallel calculation.

### Part 2 (Optional)

- Create a "verifie" script to check the resulting value (sequential then parallel).
- Add a call to "compare sonde" in your "verifie" script...

#### Part 3

- To validate parallelization in TRUST, you can use the command "compare lata":
  - \$ ls \*lata
  - \$ compare\_lata Cx.lata PAR\_Cx.lata

### Part 3

- You can see that there is no differences and the maximal relative error encountered is about 4.e-12.
- Performances \$ 1s \*TU
  - \$ meld Cx.TU PAR\_Cx.TU &
  - \$ meld Cx\_detail.TU PAR\_Cx\_detail.TU &

#### Part 4 Debog

- Copy a debog test case:
  - \$ cd \$project\_directory/build
  - \$ trust -copy Debog\_VEF
  - \$ cd Debog\_VEF
- Open the Debog VEF.data file and search the "Debog" command.
- Sequential run:
  - \$ trust Debog\_VEF
- You get "seq" and "faces" files.

### Part 4 Debog

- Partitionning step and creation of the parallel data file:
  - \$ trust -partition Debog\_VEF 2
- $\bullet$  Verify the parallel data file, you must have now "Debog pb seq faces 1.e-6 1".
- Run in parallel:
  - \$ trust PAR\_Debog\_VEF 2
- You get debog\*.log and DEBOG files.
- If a value of an array differs between the two calculations and the difference is greater than 1.e-6 then "ERROR" message appears in the log files else we will get "OK" (cf debog.log).
- Add a debog instruction in your file mon\_main.cpp located in \$project\_directory/TRUST\_modif, after the "Hello world" prints put: double var = 2.5; Debog::verifier("- Debog test message",var);
- Do not forget to add the "#include <Debog.h>"!

### Part 4 Debog

- Then compile and do the sequential run.
- You can see a first message.
- Then do the parallel run and check the debog.log file.
- Becarefull the debog instruction in the data file must be between the "Discretize" and "Read pb" lines.
- For more information:
  - \$ trust -doc &
  - → Open the TRUST Generic Guide
  - → Click onto the TRUST Reference Manual
  - $\rightarrow$  Search for "Debog" keyword.

- TRUST initialization
- 2 Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
- Creation of a Baltik project
  - Creation of a Battix proje
     Creation of your git
  - repository

# New share/Validation/Rapports\_automatiques

#### Baltik commands

- Create a new prm file:
  - \$ cd Formation\_TRUST/yourname/upwind
  - \$ trust -prm upwind
- Now you have a upwind.prm file.
- You have to add this prm validation file in your baltik:
  - \$ cd \$project\_directory
  - \$ cd share/Validation/Rapports\_automatiques
- Create a new repository for your new prm validation form:
  - \$ mkdir -p upwind/src
- Add the needed files (data file, mesh & .prm file):
  - \$ cp Formation\_TRUST/yourname/upwind/upwind.data upwind/src
  - \$ cp Formation\_TRUST/yourname/upwind/upwind.geo upwind/src
  - \$ cp Formation\_TRUST/yourname/upwind/upwind.prm upwind/src

# New share/Validation/Rapports\_automatiques

#### Git commands

- Add it to your git repository:
  - \$ git add upwind
  - \$ git commit -m "New prm"

#### Baltik commands

- Run this prm:
  - \$ cd upwind/
  - \$ Run fiche
- Open the pdf report:
  - \$ evince build/rapport.pdf &

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse
  - Creation of a Baltik project
    - Creation of your git
    - repository
    - Builds
    - Using Eclipse
- Modify the cpp sources
  - Create a new cpp class
  - Modify your cpp class
  - Add XData tags
  - Adding prints

- Parallel exercise
- PRM file and validation test case
  - "trust -prm"
- Validation test case
- Code coverage exercise
- Tools
  - Debug with GDB
  - Find memory bugs with valgrind

#### Baltik commands

- Create automatically the non-regression test case:
  - \$ cd \$project\_directory
  - \$ make check\_optim
    - Creation of upwind jdd1
    - Creation of upwind jdd1/lien fiche validation
    - Extracting test case (upwind.data) ... End.
    - Creation of the file upwind jdd1.lml.gz

ullet You can see in the report table that PAR upwind jdd1 has crashed: "CORE" message.

#### Git commands

- Lets check the git status before solving this problem:
  - \$ git status -uno
- A new test case based on your PRM file has been created in the directory: \$project\_directory/tests/Reference/Validation/upwind\_jdd1

### Baltik commands

- Now we want to correct the error, so copy the test case:
  - \$ cd \$project\_directory/build
  - \$ trust -copy upwind\_jdd1

#### ERROR...

- We have to re-run the configure script to take into account the new test case:
  - \$ cd \$project\_directory
  - \$ ./configure
  - \$ cd build
  - \$ trust -copy upwind\_jdd1

### Baltik commands

- Now we will analyse the error:
  - \$ cd upwind\_jdd1
  - \$ trust -partition upwind\_jdd1
  - \$ trust PAR\_upwind\_jdd1 2
- Correct the data file PAR\_upwind\_jdd1.data and re-run it.
- If it's ok, update the data file in \$project\_directory/share/Validation/Rapports\_automatiques/upwind/src ("Scatter ../upwind/DOM.Zones dom" → "Scatter DOM.Zones dom")
- To Relaunch the last test cases which do not run:
  - \$ cd \$project\_directory
  - \$ make check\_last\_pb\_optim Changement du jeu de donnees...

suite a une modification d'un jeu de donnees de la fiche de validation associee.

...

Successful tests cases :1/1

#### Git commands

Add this non-regression test in configuration:

```
$ git status -uno
$ git add
tests/Reference/Validation/upwind_jdd1/upwind_jdd1.data
```

• Commit the modifications on your git repository:

```
$ git commit -m "New reference test"
```

\$ git log

#### Baltik commands

- To run all the non regression tests with a optimized binary:
  - \$ make check\_all\_optim
- To run all the non regression tests with a debug binary:
  - \$ make check\_all\_debug
- To create an archive to share your work:
  - \$ make distrib
  - \$ 1s
- You have now an archive in tar.gz format of your baltik project.

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse
  - Create TRUST platform project under Eclipse

    - "trust -prm"
    - Validation test case
- Code coverage exercise
- Tool
  - Debug with GDB
  - Find memory bugs with valgrind

## Code coverage exercise

- We want to run test cases using rational Runge-Kutta scheme of ordre 2.
  - For this go to the Doxygen documentation of RRK2 class to see the methods of this class.
  - Use the "trust -check function|class|class::method" command to find and launch tests cases.
  - For example:
    - \$ trust -check RRK2::RRK2

- TRUST initialization
- Eclipse initialization
  - Download& configure eclipse

  - Debug with GDB
  - Find memory bugs with valgrind

## Debug with GDB

### With Eclipse:

Run a test case with GDB:

- $\rightarrow$  "Debug As" and "Debug configurations..." from "my\_project"
- $\rightarrow$  in "Arguments", "Program arguments:" upwind
- → "Working directory:" Formation TRUST/yourname/upwind/
- ightarrow "Apply" and "Debug"

For more information about GDB commands, refer to the help menu.

### Or in a terminal:

- Run a test case with GDB:
  - \$ cd Formation\_TRUST/yourname/upwind/
  - \$ exec=\$exec\_debug trust -gdb upwind
- You are now in GDB.
- Add a breakpoint and stop into the SSOR preconditionner: (gdb) break SSOR::ssor

## Debug with GDB

- Run the test case: (gdb) run upwind
- Have a look at the stack (gdb) where
- Go to the next instruction: (gdb) n
- Print an array: (gdb) print tab1
- (gdb) print tabl
- Or print matrice.tab1\_ if "optimized out" message printed: (gdb) print tab1[10]
- Print only a value of an array:

```
(gdb) dumpint tab1 # Dump the array
```

- (gdb) print tab1.size\_array() # Array size
- (gdb) up
- (gdb) list 100

### Debug with GDB

• Print lines after the 100th line: (gdb) print matrice (gdb) print matrice.que\_suis\_je() # Kind of matrix ? (gdb) print matrice.que\_suis\_je().nom\_ # Kind of matrix ? (gdb) up 5 # Move up 5 levels (gdb) list 900 Print others variables: (gdb) # Pressure field (gdb) print la\_pression.que\_suis\_je().nom\_ (gdb) # Pressure values (DoubleTab) (gdb) print la\_pression.valeurs() (gdb) # DoubleTab dimension (gdb) print la\_pression.valeurs().nb\_dim() (gdb) # Dump the field values (gdb) dumptab la\_pression.valeurs()

- TRUST initialization

    - "trust -prm"
    - Validation test case
- Code coverage exercise
- Tools
  - Debug with GDB
  - Find memory bugs with valgrind

## Find memory bugs with valgrind

- Run a test case with Valgrind:
  - \$ cd \$project\_directory
  - \$ source env\_my\_project.sh
  - \$ cd build/Cx/
  - \$ VALGRIND=1 trust Cx
- The Valgrind messages appear on the screen with the beginning of each line the same number. For example:
  - \$ ==26645== ...
- The last line indicates if errors have occurred. An example with 0 error:
  - \$ ==26645== ERROR SUMMARY: 0 errors from 0 contexts
    (suppressed: 0 from 0)
- Now we will modify the sources in your baltik project to generate a Valgrind error on the Cx test case.

# Find memory bugs with valgrind

- Edit the "my\_first\_class.cpp" file and remove the initialization of the sum to calcule the total of control volumes.
   In place of "double sum=0;", put only "double sum;".
- Rebuild your project and run the test case:
  - \$ cd \$project\_directory
  - \$ make debug optim
  - \$ cd build/Cx/
    - o in mode optim:
      - \$ exec=\$exec\_opt trust Cx
        In this case, no error appears.
      - o in mode debug:
        - \$ exec=\$exec\_debug trust Cx
          In this case also, no error appears.
      - in mode valgrind:
        - \$ VALGRIND=1 exec=\$exec\_opt trust Cx
          On the other hand, in this case, there are errors.
        - \$ ==7517== ERROR SUMMARY: 187 errors from 109 contexts
